

Can using copper links for computing power reduce the need for optical modules

Overview

A shorter path eliminates the need for the high-power retimers and other signal-conditioning components required for long-reach copper traces, dramatically reducing the power consumed by the optical I/O. Today, links are running at 1 Tbps over optical, or 10,000 times faster than cutting edge speeds two decades ago. “Every single large language model today runs on compute clusters that are enabled by Marvell’s connectivity silicon,” said Achyut Shah, senior vice president. While copper cabling still offers cost and reliability advantages for short-distance connections, it faces the dual challenges of speed bottlenecks and cabling complexity in high-bandwidth, long-distance, and high-energy-efficiency scenarios. They traffic data between racks, using pluggable transceivers that convert electrical signals into optical ones. To improve energy. This revolution is profoundly impacting the physical realities of data centers, pushing the boundaries of how much power, cooling and interconnect bandwidth is required. We demonstrate an end-to-end MOSAIC prototype with 100 optical channels, each transmitting at 2 Gbps, and show how it scales to 800 Gbps and (b) Optical. With energy requirements for copper far higher than fiber, data center engineers are taking a closer look at picojoule per bit numbers. Adding to the fiber case is reach.
