

Principle of Optical Fiber Communication Reflection

Overview

Optical fiber uses the optical principle of "total internal reflection" to capture the light transmitted in an optical fiber and confine the light to the core of the fiber. An optical fiber is comprised of a light-carrying core in the center, surrounded by a cladding that acts to traps light in the. Optical fibers are circular dielectric wave-guides used to contain and transmit light over short or long distances. They consist of three elements as shown in Figure 1: a central core, cladding and a protective coating. The device or a tube, if bent or if terminated to radiate energy, is called a waveguide, in general. The electromagnetic energy travels through. Optical Fiber Cable (OFC) is considered the backbone of network connectivity. It occurs when light hits a boundary between two media with different refractive indices at a certain angle, causing the light to be completely reflected. Fiber-optic communication is a method of transmitting data from one point to another by sending infrared light pulses through an optical fibre.
