

Wavelength Division Multiplexing Transmission Direction

Overview

Normal WDM (sometimes called BWDM) uses the two normal wavelengths 1310 and 1550 nm on one fiber. Dense WDM (DWDM) uses the C-Band (1530 nm-1565 nm) transmission window but with denser. In fiber-optic communications, wavelength-division multiplexing (WDM) is a technology which multiplexes a number of optical carrier signals onto a single optical fiber by using different wavelengths (i. It involves transmitting light of different rates mixed together within a single optical fiber, where the digital signals carried by these light signals of different wavelengths can be. There are two common technologies used to multiplex two wavelengths in one fiber: fused biconical tapered fiber (FBTF) and free space optics (FSO). FBTF type WDM costs less but offers limited optical performance (~17 dB isolation). This makes it possible to scale capacity cost-effectively by using existing infrastructure more efficiently.
