

What is optical module jitter

Overview

Jitter in optics causes image blur and data errors in optical systems. This imperfection is known as jitter, and it's one of the most significant factors determining the performance and reliability of your network. 5 dB for filter on/off should result in much better BER than $\sim 4E-5$ irrespective of jitter! – However neither TDECQ (except CER_TDECQ). Output jitter is the total jitter measured at the output of a system, specified in unit intervals (UI). One UI corresponds to an amplitude of one clock period, independent of bit rate and signal coding, displays results as a peak-to-peak value or root mean square (RMS) value over a defined. Jitter is a critical parameter in optical networks that can significantly impact the quality and reliability of high-speed data transmission. These effects decrease the time available for error-free data recovery by reducing the received "eye opening" of nonreturn-to-zero (NRZ). As optical fiber technology continues to push the limits of data transport speed and efficiency, the challenge falls on silicon SerDes vendors to keep up.
